## **1. INTRODUCTION**

Cargo Manager is a comprehensive cargo management module, designed for addressing the areas of General cargo, Bulk cargo operations. All the aspects of cargo like documentation handling, movement, and storage are addressed in this module.

### **Key Features Include**

- General Cargo Booking (Manifestation of cargo)
- Storing of Cargo (actual cargo weight, volume etc. are recorded)
- Generating the gate pass for bringing the cargo into the warehouse
- Marking the truck exit
- Delivery order for rejected or damaged cargo
- Generating gate pass for redelivery of cargo
- House keeping movements for maintenance i.e., moving the cargo from one place to another
- Extensive report and querying facilities
- Creation of master like cargo agents, commodity master.

### **Managing The Data**

The fundamental building blocks to cargo revenue maximization begin with sufficient, reliable and accessible data. Full air waybill capture is a good starting point. The waybill history should be stored in an accessible format in a database that can be updated daily.

The real challenge is not just to capture the complete life cycle of a shipment from original booking through to invoicing, but to do so in a dynamic and timely way. With new developments in data handling and communications, it is now possible to build a data warehouse that receives seamless, real time updates from reservation systems and with minimal changes to existing systems.

## **Unconstrained Demand**

Shipment dimensions cannot be given accurately at the time the booking request is made. Often the actual dimensions received at tender do not anyway become part of any permanent record. Since flights will reach their volume limitations before they hit weight limits on some sectors, some heuristic calculation, such as a density code, is needed to forecast likely volumes. The first step is to use historic data to gauge the total market demand regardless of the airline's available capacity. This unconstrained demand is set for each product type by origin and destination (O&D), day of week, time of day.

Most cargo customers, unlike passengers, are more concerned with speed and reliability than with routings. That gives the cargo carrier an opportunity to route shipments away from congested bottlenecks and give a better spread of revenues across the network.

For example, a booking request comes through the reservation center to ship between a hub airport and major destination. The route is consistently oversold, so the bid rate is high. The router will evaluate alternative feasible routes which meet both the shipper's requirements and the carrier's business rules.

## **Removing The Politics**

Effectively, the cargo revenue optimization system will allow decisions to be taken that make optimal use of another, then the choice will not be made. There will be times when the users override the system's decisions, but overall it provides the basis for objective network-wide decision-making, taking away the guesswork and the politics.

## **Tools**

You can use Oracle as back-end database and VB.NET / Java to develop the project.

## **2. DESIGN PRINCIPLES & EXPLANATION**

### **2.1. MODULES**

#### **Data Requirements**

- **Packing Options**
- **Cargo Summary Screen.**

### **2.2. MODULE DESCRIPTION**

#### **Data Requirements**

CARGOMANAGER requires as input details of the cargo items forming the load and of the available container / containers (or truck, trailer, frame pallet etc.) which might be used for the load. Much of this information relates to dimensions and weights, and additional information can optionally be provided on the characteristics of each cargo item type (fragility, layering constraints etc).

This input can be carried out in two ways:

**Direct screen data entry** uses a set of windows screens linked to CARGOMANAGER database files (for user specified container and product information), to provide for input of information with the minimum of effort.

Alternatively, as described later, it is possible to **link CARGOMANAGER to other systems** (say an AS400 data entry system) so that data already held in other systems can provide full or partial input into the software.

## **Direct Screen Entry.**

CARGOMANAGER requires user entry of container and product dimensions, together with information on weight and orientation constraints. In-built database facilities for up to 50 containers and 4000 products are provided so that input into these screens can be carried out with minimal effort. If information for a particular product code is already held in the 4000 product database then this is automatically entered into the appropriate fields.

In addition, placement and priority information can be provided for each item in the consignment. This allows CARGOMANAGER to deal with the realities of the loading bay - heavy and fragile cargo, items which will arrive late, multi-drop consignments and 'filler' items which are loaded last to fill any remaining space.

The values entered above have a very significant impact on the quality of the loading arrangements achieved. Before specifying the orientation, heavy, fragile and number of layers values at a value OTHER THAN their defaults the points detailed should be considered

Also, when loading a single product into a container / pallet, you will be presented with the dialogue . One of three options may be selected.

The first of these will attempt to pack as much of the cargo using any of the packing methods available to CARGOMANAGER. This may be a loading from the floor or from the end of the container. The second and third options are self explanatory and the one most appropriate to the practical circumstances should be selected.

Once input is complete, a summary of input information is provided (which might result in a user deciding to return to add items to the consignment), before the (optional) saving of the data file, and the subsequent packing of the cargo is carried out.

### Input Data Summary

Once input is complete a summary of the input data is provided (which might result in a user deciding to return to add items to the consignment or change the initial container size selected). Alternatively the cargo can then be packed into one (or multiple) containers with a 'click of the mouse', **or** the efficiency of loading the cargo into **any / all** of the user defined container / trailer sizes held by system can be carried out in matter of seconds.

If data entry is complete, the consignments details can be saved to disk for subsequent recall and modification, before the packing of the container(s) is carried out. The user can at this stage select whether the given load should be packed into a single container or if a multiple container loading is required.

### **PACKING OPTIONS.**

In order to meet the needs of a specific application some degree of 'tailoring' may be required. The Packing Options screen provides this facility. It should be noted that changes to these values are unlikely to be required on a regular basis, and once set they may well not require any subsequent change.

Following the display of the Summary of Input Data you may select to pack immediately the specified cargo or alternatively select **Options** to display the Packing Options Screen. The Options screen allows you to control the way in which packing is carried out. If you choose to move

directly to Packing then the previous (or Default) option settings remain unchanged.

The settings on this screen are very important in obtaining solutions appropriate to your needs and the description below of the parameters and their effect should be read with some care. Once set they may well not require any subsequent change.

During the packing some of the important things are to be noted such as:

- Apply priorities as a strict ranking?
- Restrict packing to Columns?
- Partially remove constraints on heavy/fragile items?
- Should the drawing produced be sectional?
- Should packing be layered from the floor up?
- Attempt layered solutions when leveling?
- Once a complete packing has been achieved CARGOMANAGER still continues to perform calculations for some time.
- The cargo has to be dropped off at a number of points en route and the loading arrangement used should accommodate this.
- Priority Values for Multi-drop loads.

## **THE CALCULATION PHASE.**

Once data entry is complete the Calculation Phase of **CARGOMANAGER** will then commence.

**CARGOMANAGER** makes use of a wide range of methods so as to obtain a cargo packing which makes maximum use of the volume of the container. If the cargo CAN be fitted then the length of the container used is minimized, if it cannot then the arrangement which

maximizes the volume packed is selected. If the packing is constrained by weight then appropriate messages will be output on both screen and printer and the weight of cargo packed will be restricted so as to meet the stated weight constraint.

The calculations are carried out in a number of distinct stages and during each stage a very large number of possible packing arrangements are investigated. As each stage progresses the screen display shows the rate of computational progress

As outlined above there may well be situations where a **CARGOMANAGER** user wishes to restrict the number of calculations carried out - either because a solution has already been found, or because of time constraints. In doing so, the best solution found up to the point when the button was selected will be retained as the 'best' solution. If the problem is easily soluble then calculation time is likely to be fairly small, especially if the Packing Options for 'Complexity' and 'Effort once packed' have been set appropriately. This latter parameter will also, in these instances, avoid any need to utilize the Break Early button. Once calculations are complete the solution which provides the best volume utilization (subject to weight constraints) is saved

Select **Continue** to display the results in tabular form

Alternatively, having manually entered details of one or more cargo items into the input screen of **CARGOMANAGER** the **Item Base** option is available (on the Cargo Summary Screen). This option saves all Case Information associated with the current problem into the database, updating any existing records with the new data. During data entry, after entry of each product description (i.e. Case code/description), **CARGOMANAGER** will normally search the database for a product match. If one is found then the details of

product size, orientation and layer constraints will be automatically entered on the data screen and the cursor positioned ready for the user to enter the quantity to be packed. The automatic database check can be switched off if required.

Prompted for a Cargo Description - which can be any text description that describes the consignment - you are then presented with the Container.

### **Cargo Summary Screen.**

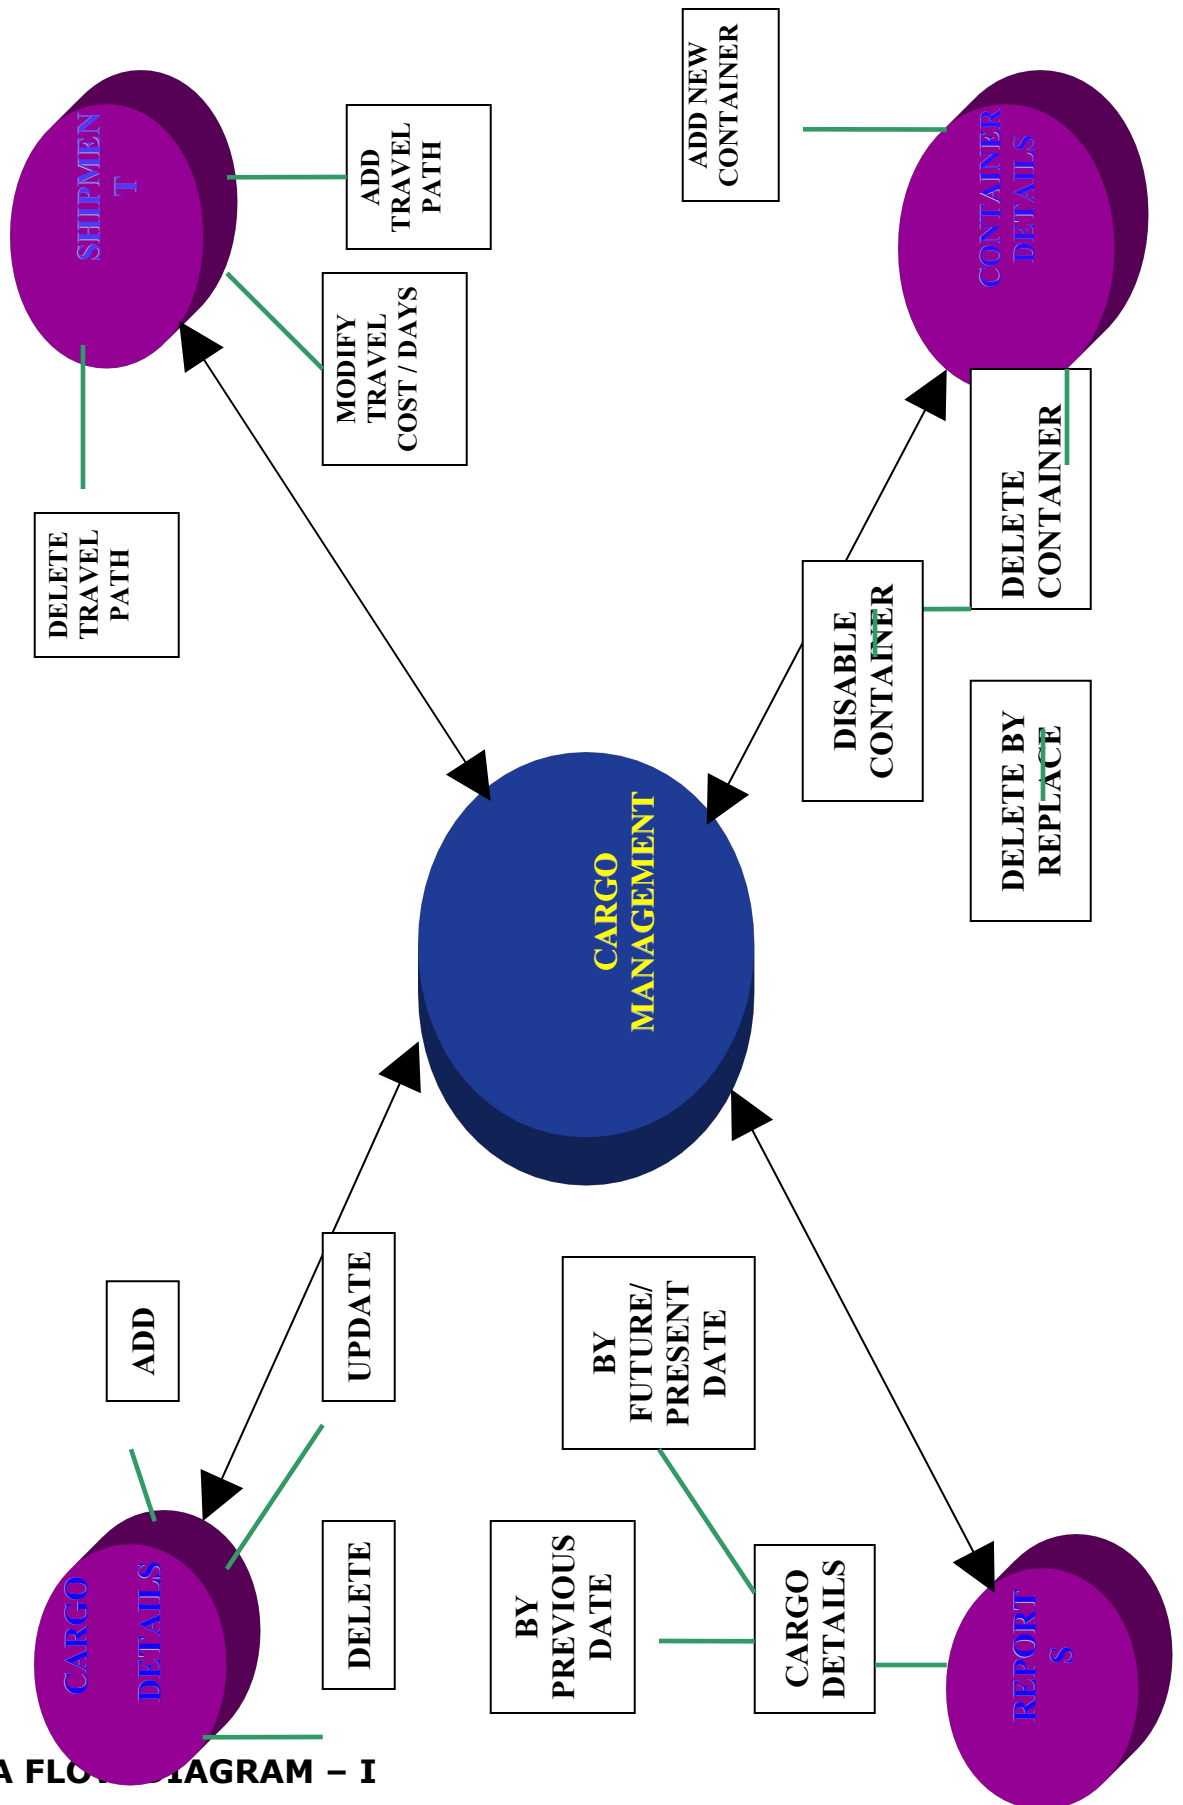

On this screen, in addition to the 'Back', 'BestCont', 'MultiCont' and 'PackCalc' options there is the 'Options' button. This allows users to tailor the packing rules used by **CARGOMANAGER** to suit their particular loading environment

As described on screen BestCont enables loading comparisons to be obtained for loading single container loads and MultiCont deals with multiple container packing using multiple identical containers of one or more sizes

If you wish at some future time to re-run **CARGOMANAGER** using the same consignment data, perhaps changing slightly the quantities or dimensions then you now have the opportunity to write details of the Container and Cargo to disk for possible future recall.

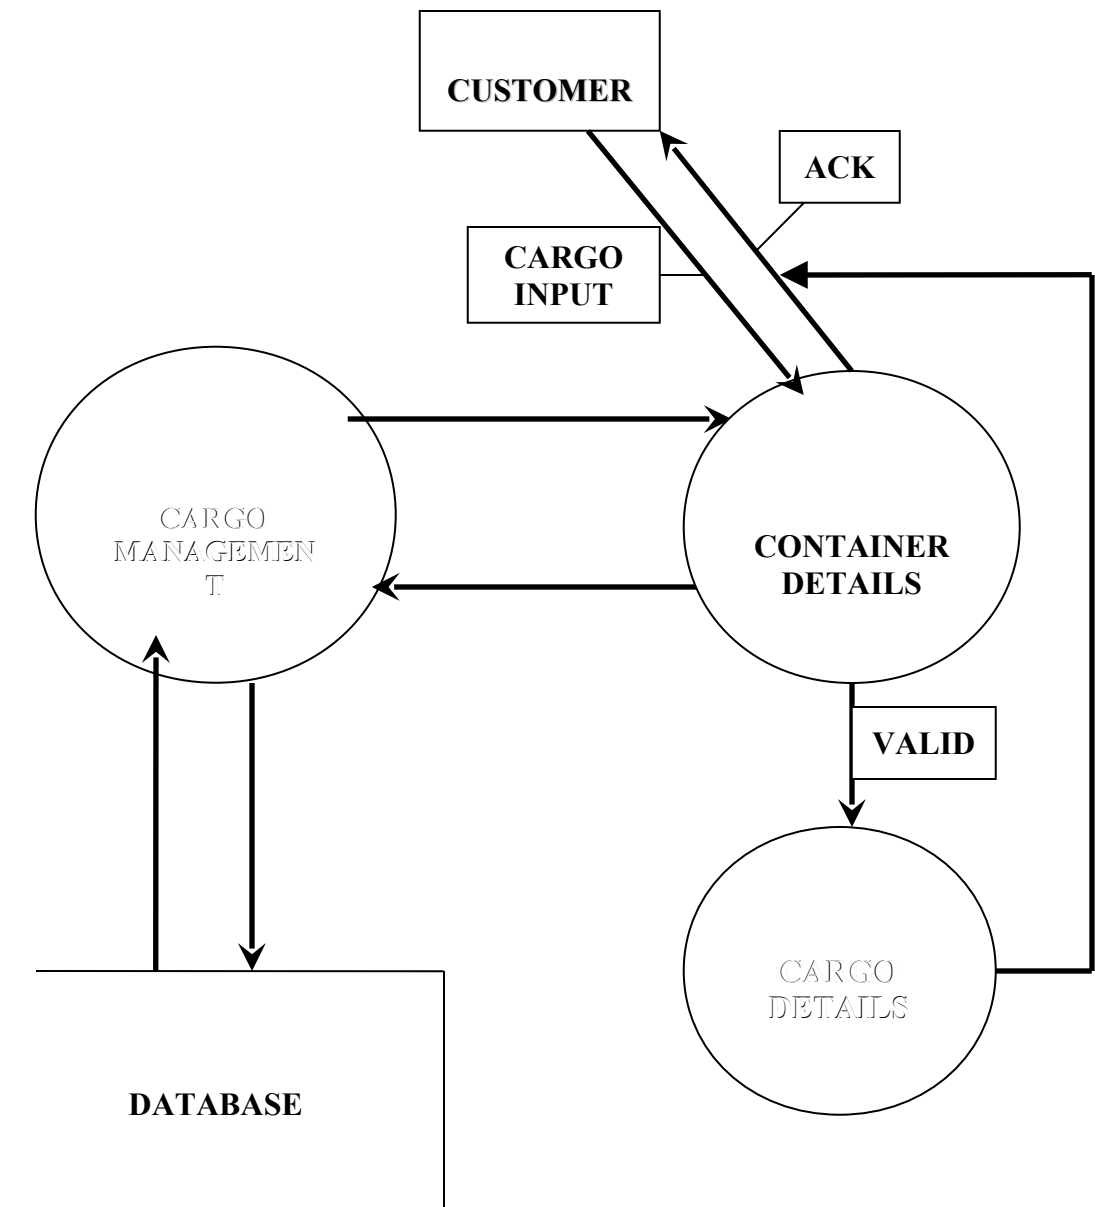

### **3. PROJECT DICTIONARY   3.1. DATAFLOW DIAGRAMS**

DATA FLOW DIAGRAM - I

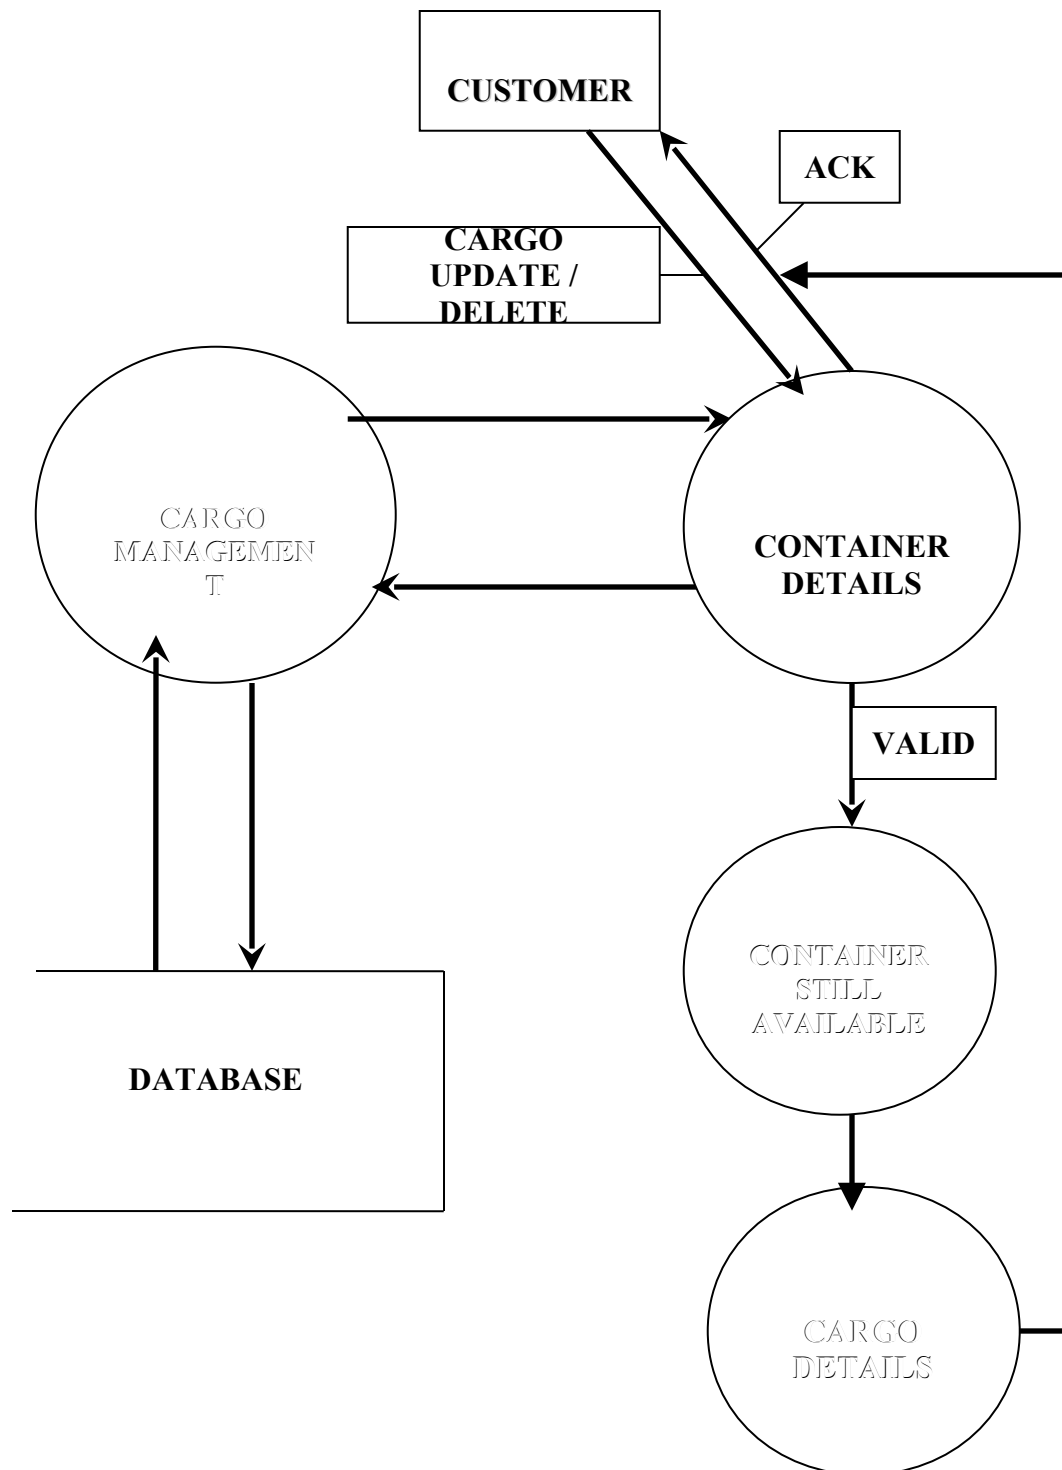

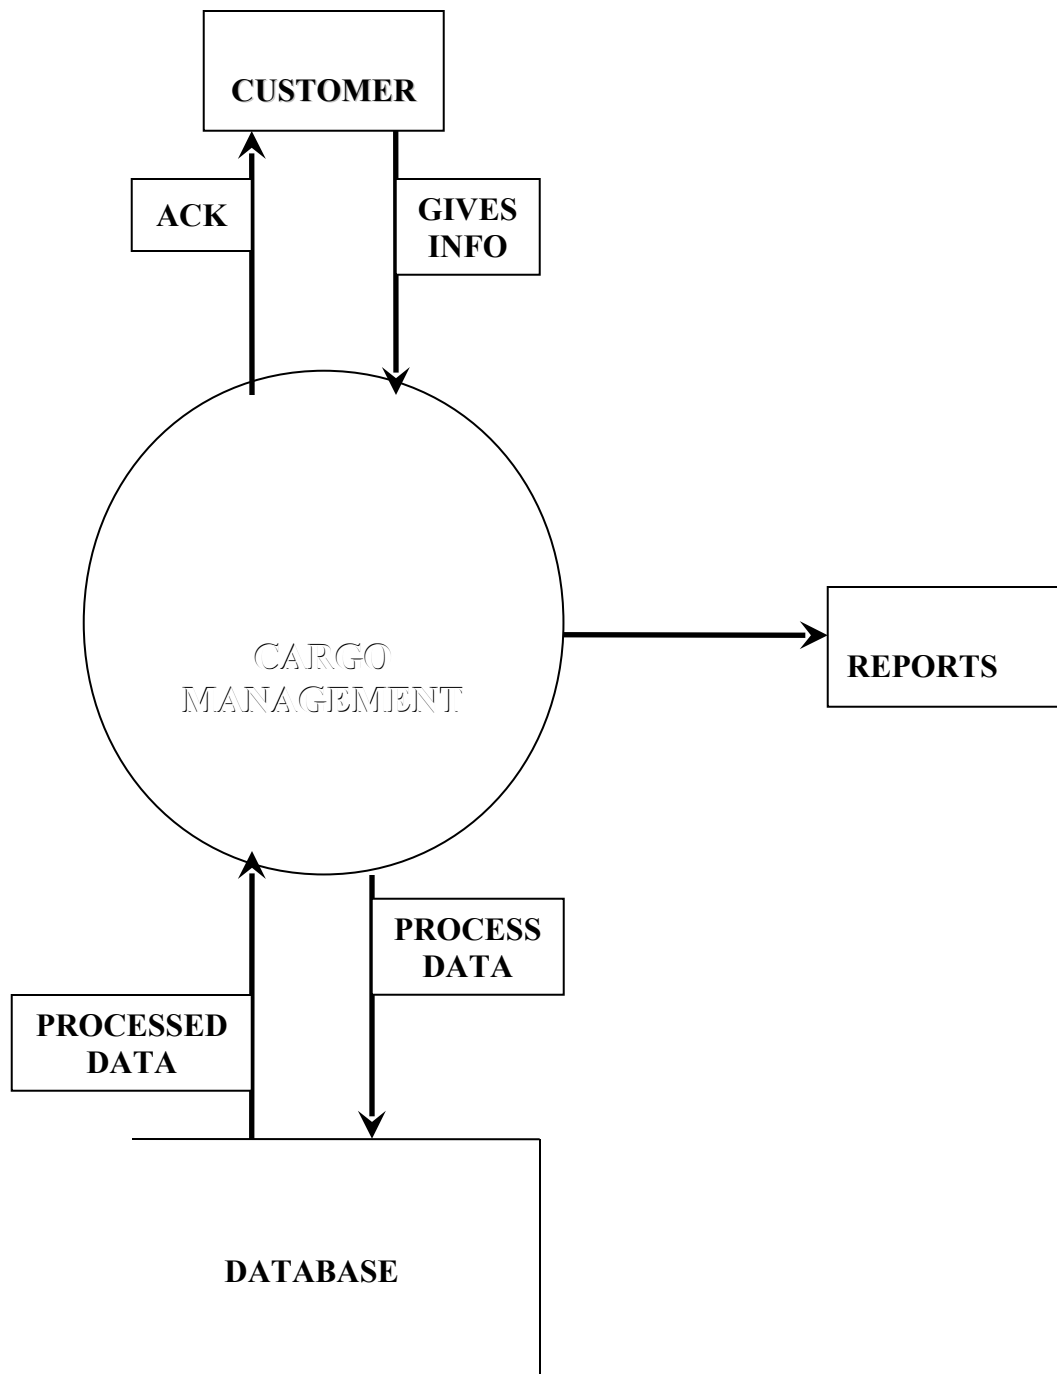

**(2.) DATA FLOW DIAGRAM – II FOR CARGO INPUT**

### **(3.) DATA FLOW DIAGRAM FOR CARGO UPDATE / DELETE**

single use case. It shows the objects and the messages that are passed between these objects in the use case.

4.3. DATA DICTIONARY

❖ SHIPMENT TABLE

SOURCE: - The place from where the cargo has to leave from.

DESTINATION: - The place where the cargo has to reach.

TRAVELCOST: - Calculating or computing the cost of the journey of the cargo from source to destination.

DAYS: - Number of days of journey.

#### ❖ **CONTAINER TYPE TABLE**

CONTAINERNAME: - Name of the container in which goods are carried.

CONTAINERLEN: - Length of the container.

CONTAINERWID: - Width of the container.

CONTAINERHEI: - Height of the container.

CONTAINERWEIGHT: - Weight of the container.

CONTAINERCAP: - Capacity of the container.

#### ❖ **CONTAINER DETAILS TABLE**

CONTAINERID: - Identification number of the container In which the goods are carried.

CONTAINERDESC: - Description of the container.

CONTAINERSOURCE: - Starting point of the container is the container source.

CONTAINERDESTINATION: - To which place has the container reached, is the container destination.

#### ❖ **CONTAINER SPACE TABLE**

CONTAINERFROM: - Is similar to CONTAINERSOURCE.

CONTAINERTO: - Is similar to CONTAINERDESTINATION.

CONAVAILABLE: - The availability date of the container.

CONSPACE: - The space in the container.

#### ❖ **CARGO DESCRIPTION TABLE**

CARGODATE: - On which date the cargo has to leave from source and reach the Destination.

CARGOID: - Identification number of the cargo.

CARGODESC: - Description of the cargo.

CARGOFROM: - Starting point of the cargo or from where the cargo is coming from is CARGOFROM.

CARGOTO: - To which place the cargo has to reach, is The CARGOTO.

❖ **CARGODIMEN TABLE**

CARGOLEN: - Length of the cargo.

CARGOWID: - Width of the cargo.

CARGOHEI: - Height of the cargo.

CARGOWEI: - Weight of the cargo.

CARGOQUA: - Quantity of the cargo.

❖ **CARGOWEIGHT TABLE**

CARGONETWEI: - Net weight of the cargo.

CARGONETCAP: - Net capacity of the cargo.

CARGONETCOST: - Net cost / Total cost for the cargo.
